Problem Set 2

Fall 2021

1. **Among Us**

   In the game of Among Us, there are 9 players. 4 of them are imposters and 5 of them are crewmates. There is also a deck of 17 cards containing 11 "sabotage" cards and 6 "task" cards. Imposters want to play sabotage cards, and crewmates want to play task cards. Here's how the play proceeds.

   - A captain and a first mate are chosen uniformly at random from the 9 players.
   - The captain draws 3 cards from the deck and gives 2 to the first mate, discarding the third.
   - The first mate chooses one to play.

   Now suppose you are the first mate, but the captain gave you 2 sabotage cards. Being a crewmate, you wonder, did the captain just happen to have 3 sabotage cards, or was the captain an imposter who secretly discarded a task card. In this scenario, what's the probability that the captain is an imposter? Let's assume that imposter captains always try to discard task cards, and crewmate captains always try to discard sabotage cards.

2. **Lightbulbs**

   Consider an $n \times n$ array of switches. Each row i of switches corresponds to a single lightbulb L_i, so that L_i lights up if at least i switches in row i are flipped on. All of the switches start in the "off" position, and each are flipped "on" with probability p, independently of all others. What is the expected number of lightbulbs that will be lit up? Express your answer in closed form without any summations.

3. **Compact Arrays**

   Consider an array of n entries, where n is a positive integer. Each entry is chosen uniformly randomly from $\{0, \ldots, 9\}$. We want to make the array more compact, by putting all of the non-zero entries together at the front of the array. As an example, suppose we have the array

   $$[6, 4, 0, 0, 5, 3, 0, 5, 1, 3].$$

   After making the array compact, it now looks like

   $$[6, 4, 5, 3, 5, 1, 3, 0, 0, 0].$$

   Let i be a fixed positive integer in $\{1, \ldots, n\}$. Suppose that the ith entry of the array is non-zero (assume that the array is indexed starting from 1). Let X be a random variable which is equal to the index that the ith entry has been moved after making the array compact. Calculate $\mathbb{E}[X]$ and $\mathrm{var}(X)$.

4. **Borel-Cantelli & Strong Law**

In this problem, we walk through a proof of the strong law (assuming finite 4th moments) that relies only on basic probability. In class we covered the *Borel-Cantelli lemma*, which states that for events $(A_n)_{n=1}^{\infty}$, if $\sum_{n=1}^{\infty} P(A_n) < \infty$, then

$$P(A_n \text{ i.o.}) = 0,$$

where we define the event $\{A_n \text{ i.o.}\} = \cap_{n \geq 1} \cup_{m \geq n} A_n$ as the event where infinitely many A_n occur.

(a) Let $X_1, X_2, \ldots$ be i.i.d. with $\mathbb{E}X_i = 0$ and $\mathbb{E}X_i^4 < \infty$ (and so we also have finite second and third moments). Let $S_n = X_1 + \cdots + X_n$, and compute $\mathbb{E}[S_n^4]$. Write your answer in terms of the moments $\mathbb{E}[X_i^2], \mathbb{E}[X_i^3], \mathbb{E}[X_i^4]$.

(b) Fix an $\epsilon > 0$, and use Markov's inequality to show that, for any n,

$$P(|S_n/n| > \epsilon) \leq O(n^{-2}).$$

(c) Finally, use Borel-Cantelli to conclude that $P(\lim_{n \to \infty} S_n/n = 0) = 1$. This a weaker (the full theorem assumes only finite first moments) form of the *strong law of large numbers*.

5. **Bounds for the Coupon Collector's Problem**

Recall the coupon collector's problem, where each box contains a single coupon, and there are n different types of coupons. We let X be a random variable which is equal to the number of boxes bought until one of every type of coupon is obtained.

The expected value of X is nH_n, where H_n is the *harmonic number of order n* which is defined as

$$H_n \triangleq \sum_{i=1}^{n} \frac{1}{i},$$

and satisfies the inequalities

$$\ln n \leq H_n \leq \ln n + 1.$$

(a) Use Markov's inequality in order to show that

$$P(X > 2nH_n) \leq \frac{1}{2}.$$

(b) Use Chebyshev's inequality in order to show that

$$P(X > 2nH_n) \leq \frac{\pi^2}{6(\ln n)^2}.$$

   Note: You can use the identity

$$\sum_{i=1}^{\infty} \frac{1}{i^2} = \frac{\pi^2}{6}.$$

(c) Define appropriate events and use the union bound in order to show that

$$P(X > 2nH_n) \leq \frac{1}{n}.$$

   Note: The sequence $a_n = (1 - 1/n)^n$, for $n = 1, 2, 3, \ldots$, is strictly increasing and $\lim_{n \to \infty} a_n = 1/e$.
